Abstract
Surface sound speed (SSSP) of the seawater was studied for the low salinity region in the East China Sea during the summer monsoon season. Sea surface temperature (SST) from NASA’s AMSR-2 and sea surface salinity (SSS) from ESA Soil Moisture and Ocean Salinity (SMOS) mission were implemented. In this research, using sound speed formula, the advent of Acoustic Channel due to the unpredictable expansion of Changjiang River born freshwater was speculated by comparing SSSP with subsurface sound speed from numerically predicted salinity and temperature. Because the Acoustic Channel is created below the surface when the SSSP is lower (i.e. extremely low salinity or low temperature) than subsurface, its horizontal distribution may provide good understanding of the acoustical impact of expanding freshwater into the open ocean.

Background
Underwater acoustic channel in the west coast of Jeju Island in the summer season

Outflowing Changjiang River (CR) plume with a thickness of 10-15m depth has potential to result underwater acoustic channel near the west coast of Jeju Island during the summer season (Kim et al., 2013). This research estimated the sound speed (SSSP) in the East China Sea (ECS) using passive microwave remote sensing and mapped the spatial distribution of the acoustic channel in August, 2014.

b. Flagging level-2 SMOS SSS considering radio frequency interference (RFI)/land contamination
: see Appendix C in Kil (2015)

c. Sound speed (SSSP) by Medwin, (1975): 
SSP(m/sec) = 1449.2 + 4.6T – 0.55T^2 + 0.00029T^3 + (1.34-0.01T)(S-35) + 0.016Z

T : Temperature (°C), S : Salinity (psu), Z : Depth (m)

d. ∆SSSP : SSP_{mon} – SSP_{min}

SSP_{mon} : Surface sound speed (SSSP), SSP_{min} : SSP at depth 10m estimated by HYCOM (SSP_{HYCOM}(10m))

Potential acoustic channel in the ECS : ∆SSP < -0.2 m/sec (Kim et al., 2013)

4. Conclusion
Acoustic sound channel in the ECS which is rarely appeared in the numerical model was successfully presented as moving toward Jeju Island by using passive microwave remote sensing satellite AMSR-2 and SMOS. Replacing predicted SSS and SST by satellite born SSS and SST resulted lower sound speed than 10m depth of the modeled sound speed on the low salinity dominated CR mouth. SMOS’s capability to measure the low salinity water contributed estimating better realistic surface sound speed than modeled one.
